

# CPT109: C Programming & Software Engineering I

## Lecture 2: Fundamentals of C Programming

Dr. Xiaohui Zhu

Office: SD535

Email: [Xiaohui.zhu@xjtlu.edu.cn](mailto:Xiaohui.zhu@xjtlu.edu.cn)

# Outline of Today's Lecture (week 2)

- First program review...
- C-Language Data
- Variables and Constants
- Computational Problems
- Characters, Arrays and Strings
- C Fundamentals
- Basic Input/Output Functions

---

**That first program again...**

---

# Your first C program (1/3)

```
#include <stdio.h>
```

```
int main (void)
```

```
{
```

```
    printf("Programming in C is fun.\n");
```

```
    return 0;
```

```
}
```

**Q.** What does this C program do?

# Your first C program (2/3)

The previous C program consists of two parts:

- A **preprocessor directive** (begins with #)
- The **main** function.

## Preprocessor directives

- Are commands that give instructions to the C preprocessor, whose job is to modify the text of a program before it is compiled.
- Begin with the # character
- Two commonly used directives
  - **#include**
  - **#define**

# Your first C program (3/3)

The **main()** function:

- Every program has a main function
- C program execution begins with the main function

# The #include Directive

**Syntax:** `#include` <header file>

**Examples:**

`#include` <stdio.h>      `#include` <math.h>

**Interpretation:**

- Tell the preprocessor where to find the definitions of standard identifiers used in the program
- Definitions are collected in files called standard header files
- Examples:
  - `stdio.h` contains definitions of standard input/output functions such as `scanf` and `printf`
  - `math.h` contains definitions of common math functions such as `pow(2,3)` and `sqrt(4)`

# The #define Directive

**Syntax:** **#define** NAME value

## Examples:

- **#define** PI 3.141593
- **#define** MAX 100

## Interpretation:

- The preprocessor is notified that it is to replace each use of the identifier NAME by value

## Remarks:

- C program statements can not change the value associated with NAME

# The main () Function (1/2)

## Syntax:

```
int main (void)
{
    main function body
}
```

## example:

```
int main (void)
{
    printf("Programming in C is fun.\n");
    return 0;
}
```

# The main () Function (2/2)

## Interpretation:

- C Program execution begins and (normally) ends with the main function.
- Braces {} enclose the main function body which contains declarations and executable statements

## Observations:

- int main (void) indicates that the main function returns an integer value to the operating system when it finishes normal execution (the example returns zero)
- int main (void) indicates that the main function receives no parameters/functions from the operating system before execution.

---

# C-Language Data

---

# Character Set in C

The characters in C are grouped into the following categories:

## **Letters:**

UPPERCASE A...Z, lowercase a...z

## **Digits:**

0...9

## **Special Characters:**

e.g. + = - / ! : ; etc.

## **White Space:**

e.g. blank space, tab, return (enter)

# Keywords in C

Some words have fixed meanings

These meanings cannot be changed

**Must** be written in **lowercase**

Are used as basic building blocks

Around 32 Keywords, some examples:

break	case	char
const	do	else
float	for	if
int	return	sizeof
static	struct	typedef
include	void	while

# Standard Identifiers in C

These have special meaning or use in C

They can be redefined by the programmer (**NOT recommended!**)

examples:

printf

scanf

names of operations (identifiers) defined in the standard header file `stdio.h`

# User-Defined Identifiers

These refer to names of variables, functions and arrays

They are defined by the user (That's **YOU**)

Names can be chosen following these rules:

- First character **must** be a letter or underscore

- Must** only contain characters, digits, underscores

- Must **not** be a C keyword

- Must **not** contain whitespace

- Should **not** be longer than 31 characters

# User-Defined Identifiers

**Q.** Are the following examples valid identifiers:

Hello\_My\_Name\_Is\_Tom

hello\_my\_name\_is\_tom

F12345

1F2345

F12 45

---

# **Variables and Constants**

---

# Variables and Variable Declarations

## A variable:

- Is a data name that can be used to store a data value
- May take different values at different times during program execution
- Associated with a data type (i.e. character or number)

## Variable declaration:

- Tells the compiler the variable name
- Specifies the type of data the variable will hold

**Syntax:** **data\_type** name

**Examples:** **int** number; **char** name; **double** sum, total;

# Variables

- A variable is a *named memory location* that can hold a value (*in binary*)
- In C (and most languages) a variable must be declared before use.
- Declaration does 2 things:
  - Determines the type of variable
  - Reserves specific memory space for that variable

# Fundamental Data Types & ASCII

Type	Description	Bytes	Range
<b>int</b>	Integer Numbers	4	-2,147,483,648 to 2,147,483,647
<b>float</b>	Real Numbers	4	$10^{-38} - 10^{+38}$ (approx.)-6 digit precision
<b>char</b>	Characters	1	ASCII (-128 – 127)

## characters

- **ASCII** - **A**merican **S**tandard **C**ode for **I**nformation **I**nterchange
- **7-bit code** - **ANSI** (**A**merican **N**ational **S**tandards **I**nstitute) 1968

Computers only understand numbers. ASCII is the global standard numerical representation for each character. Example:

'a' = 97

'@' = 64

# ASCII

Decimal	Hexadecimal	Binary	Octal	Char	Decimal	Hexadecimal	Binary	Octal	Char	Decimal	Hexadecimal	Binary	Octal	Char
0	0	0	0	[NULL]	48	30	110000	60	0	96	60	1100000	140	`
1	1	1	1	[START OF HEADING]	49	31	110001	61	1	97	61	1100001	141	a

# Data Types and Ranges

Data Type	Description	Bytes	Range
<b>short</b>	short integer	2	-32,768 to 32,767
<b>unsigned short</b>	positive short integer	2	0 to 65,535
<b>int</b>	integer	2 or 4	see short or long
<b>unsigned int</b>	positive integer	2 or 4	see unsigned short or long
<b>long</b>	long integer	4	-2,147,483,648 to 2,147,483,647
<b>unsigned long</b>	positive long integer	4	0 to 4,294,967,295
<b>float</b>	single precision real number	4	$1.2 \times 10^{-38}$ to $3.4 \times 10^{38}$ (6 digits of precision)
<b>double</b>	double precision real number	8	$1.7 \times 10^{-308}$ to $1.7 \times 10^{308}$ (10 digits of precision)
<b>long double</b>	double precision real number	12	$3.4 \times 10^{-4931}$ to $3.4 \times 10^{4931}$ (10 digits of precision)
<b>char</b>	character	1	-128 to 127
<b>unsigned char</b>	positive character	1	0 to 255

# Variable Initialisation

```
#include <stdio.h>
```

```
int main ()
```

```
{
```

```
    int a = 3, b; /*declare and initialise variables*/
```

```
    float x = 3.2;
```

```
    char name = 'M';
```

```
    a=4;          /*update variable value*/
```

```
    return 0;
```

```
}
```

# Constants

Refer to fixed values that can **not** change during the execution of a C program

- Using the keyword **const** before the variable declaration prevents its value from being changed.

e.g. **const int** a=7;

**const float** pi=3.141; or

**const char** msg[]="warning";

---

# Computational Problems

---

# Basic Operations

- C Provides operators for all basic mathematical functions using the standard symbols:
  - Multiply        (\*)
  - Divide        (/)
  - Subtract        (-)
  - Addition        (+)
- Constants and Variables can be operated on
- There are many additional operators that we will look at next week

# Computational Problems

- Real and integer numbers are stored differently
  - Integer – direct binary conversion
  - Real – float/double – use IEEE-754 format (power series)
- How does the computer deal with this e.g.

**float** answer;

**int** x=24, y=10;

answer=x/y;

**What value is stored in answer?**

# Computational Problems

- Real and integer numbers are stored differently
  - Integer – direct binary conversion
  - Real – float/double – use IEEE-754 format (power series)
- How does the computer deal with this e.g.

**float** answer;

**int** x=24, y=10;

answer=x/y;

**What value is stored in answer? 2.0**

**How can the correct value be obtained?**

# Type Conversions

- This refers to the changing of one data type to another
- Two type conversions: *implicit* and *explicit*
- **Why not just store everything in the same format?**

# Type Conversions

- This refers to the changing of one data type to another
- Two type conversions *implicit* and *explicit*
- **Why not just store everything in the same format?**

Data can be stored in most compact form and converted when needed

- Disadvantage

Type mismatches can be missed by the compiler

# Implicit Conversions

- When types are mixed then type conversions that can be, are performed automatically.
- Remember that a **char** is just a small integer value and can be used in mathematical operations.
- There are some rules for these conversions:

# Implicit Conversions

- **int** k=5, m=4, n; **float** x=1.5, y=2.1, z;

Context	Example	Explanation
Expression with binary operator and operands of different numeric types	k+x; value 6.5	Value of <b>int</b> variable k is converted to type <b>float</b> before operation
Assignment statement with <b>float</b> target and <b>int</b> expression	z=k/m; expression value is 1 value of z is 1.0	Expression is evaluated first. Result is converted to double for assignment
Assignment statement with <b>int</b> target and <b>float</b> expression	n=x*y; expression value is 3.15 value of n is 3	Expression is evaluated first. Result is converted to <b>int</b> for assignment. Fraction is lost.

# Explicit Conversions (**Casting**)

- You can force the use of a particular type and the implicit conversion can be ignored
- Use a **cast** operator to convert the type
- Note the **cast** does not change a value stored in a variable, it just changes the type for the calculation.

**int** age;

age=1.2+5.978; age is 7

age=(**int**)1.2+(**int**)5.978; **casts** convert values first

**age=?**

# Explicit Conversions (Casting)

- You can force the use of a particular type and the implicit conversion can be ignored
- Use a **cast** operator to convert the type
- Note the **cast** does not change a value stored in variable, it just changes the type for the calculation.

**int** age;

age=1.2+5.978; (equals 7.178) age is 7

age=(**int**)1.2+(**int**)5.978; **casts** convert values first

**age=6**

# Bindings/Precedence

```
#include <stdio.h>
```

```
int main (){
```

```
    int x=3, y=5, w, z;
```

```
    w=x+y*5;
```

```
    z=(x+y)*5;
```

```
    printf("x equals %d\n z equals %d", w, z);
```

```
    return 0;
```

```
}
```

# Bindings/Precedence

```
#include <stdio.h>
```

```
int main (){
```

```
    int x=3, y=5, w, z;
```

```
    w=x+y*5;  z=(x+y)*5;
```

```
    printf("x equals %d\n z equals %d", w, z);
```

```
    return 0;
```

```
}
```

w and z have different values

As in mathematics, operations have different binding strengths e.g. multiply (\*) stronger than add (+)

**ALWAYS** use parenthesis ( ) to ensure desired result

---

# Characters, Arrays and Strings

---

# Characters and Arrays

- Characters

Consist of any printable or non-printable character in the computers character set these include:

- lowercase/uppercase letters
- decimal digits
- special characters
- escape sequences.

Generally stored in a single byte (8-bits)

How to store words?

# Characters and Arrays

- Characters

Consist of any printable or non-printable character in the computers character set these include:

- lowercase/uppercase letters
- decimal digits
- special characters
- escape sequences.

Generally stored in a single byte (8-bits)

How to store words?

- Arrays

Ordered sequences of same type data elements

Simply put, several memory cells in a row given the same name.

# Defining an Array

- How to declare an array:

```
char name[20];
```

- This declares an array called name with 20 elements (i.e. name can store 20 characters)
- Brackets [] indicate an array
- An array **MUST** have a dimension (number of elements)
- Other examples:

```
int attendance[15];
```

```
float daily_temperature[30];
```

**What do these mean??**

# Accessing Array Elements

- How can I use each element of my array
- The first element is always **0**
- **DO NOT** exceed array bounds (no one will check!)
- Consider:

```
float price[20]; /*declare an array 20 elements*/  
price[0]=12.12; /*assign value to first element*/  
price[1]=13.13; /*assign value to second element*/
```

...

```
price[20]=12.34; /*assign value to element 20?*/
```

**What will happen here?**

# String Fundamentals

- A string is an array of characters ending with the NULL character or `'\0'`
- Can be written with double quotes `"I am a string"`
- Can be assigned when array is declared:
  - `char` `firstname[]` = `"Walter"`;
  - `char` `lastname[]` = `"White"`;
  - `char` `fullname[]` = `"Walter White"`;
- `#define` can be used to create a string
  - `#define` `TV` `"Breaking Bad"`

# String Fundamentals

- A string can also be defined by specifying individual characters:
  - `char colour[] = {'g','r','e','e','n','\0'};`
  - This shows that each character is stored in its own element.

**what would this print?**

```
printf("the fourth character is %c",colour[4]);
```

# String Library

- There is a library of string functions *string.h*
- Some examples:
  - strlen() – finds the length of a string
  - strcmp() – compares two strings character by character
  - strcpy() – copies a string from one array to another

```
#include<string.h>
```

```
#include<stdio.h>
```

```
#define NAME "Mark Leach"
```

```
main(){
```

```
printf("My name has %d characters",strlen(NAME));
```

```
}
```

---

# **C Fundamentals & Basic Input/Output Functions**

---

# Comment Lines

Comment lines are for you to give descriptive information about your code.

The C compiler ignores comment lines.

```
/* This is a C style comment */
```

```
/******
```

This is also acceptable

```
*****/
```

```
// This is C++ style DO NOT USE THIS
```

```
/* /* Nested comments cannot be used */ */
```

# Assignment Statements

```
int main (){  
    int a;           /*declarations*/  
    float x;  
    a=3;             /*assignments: a is assigned value 3*/  
    x=a+3.2;         /*what is the value of x??*/  
    return 0;  
}
```

**Syntax:** variable = expression

The equal sign (=) is called the assignment operator

Expression on the right hand side is evaluated first  
then assigned to a variable on the left hand side

# Statements

```
#include <stdio.h>
```

```
int main (){
```

```
    printf("Hello.\n");
```

```
/*statement 1*/
```

```
    printf("How are you.\n");
```

```
/*statement 2*/
```

```
    printf("I am fine.\n");
```

```
/*statement 3*/
```

```
    return 0;
```

```
/*statement 4*/
```

```
}
```

The body of main is a set of statements

Statements are instructions to the computer

The end of a statement has a semicolon ;

Blank space is ignored

Statements are executed in sequence from top to bottom

# Basic Input and Output

- Standard input functions (in `stdio.h`)
  - `getchar()` reads a character
  - `scanf()` input type must be specified
  - `gets()` reads strings
- Standard output functions (in `stdio.h`)
  - `putchar()` outputs a character
  - `printf()` output type must be specified
  - `puts()` outputs a string

# The Function printf() (1/2)

It is used to output (usually to the screen)

## Without argument

`printf("hello");` just prints letters hello

## With arguments (expressions to evaluate)

The following common format specifiers are used

Type	Specifier
int	%d
float	%f
double	%lf
char	%c
string	%s

# The Function printf() (2/2)

```
#include <stdio.h>
```

```
int main () {
```

```
    int x = 72; char b = 'Z'; float c = 3.141;
```

```
    printf("x equals %d\n",x);
```

```
        /*On the screen: x equals 72*/
```

```
    printf("b equals %c\n",b);
```

```
        /*On the screen: b equals Z*/
```

```
    printf("%d multiplied by %f equals %f", x, c, x*c);
```

```
    /*On the screen: 72 multiplied by 3.141 equals 226.152*/
```

```
    return 0;
```

```
}
```

# The scanf() function (1/2)

- reads data from the standard input device *stdin* (usually the keyboard) and stores it in a variable
- General syntax:  
scanf("format specifier", &variable);
- The ampersand (&)
  - Specifies the memory address of the variable
- example:  
int age;  
printf("enter your age:");  
scanf("%d",&age);

# The scanf() function (2/2)

- The same common format specifiers used in printf() are used in scanf() functions

Type	Specifier
int	%d
float	%f
double	%lf
char	%c
string	%s

- Add more specifiers to enter more than one argument:

**float** height, weight;

```
scanf("%f%f",&height,&weight);
```

# getchar() and putchar()

- Single character reading and writing, examples:

```
#include<stdio.h>
```

```
main(){
```

```
    char my_char;
```

```
    printf("please type a character: ");
```

```
    my_char=getchar();
```

```
    printf("\n you typed the character: ");
```

```
    putchar(my_char);
```

```
}
```

# gets() and puts()

- Multiple character reading and writing
- scanf() reads strings using the specifier %s , however it **cannot** accept the space
- If the string to be read contains spaces, either multiple reads must be made in scanf() or the gets() function **can** be used

# Example (1/2)

```
#include <stdio.h>
```

```
main()
```

```
{
```

```
char string1[50], string2[50];
```

```
printf("Enter a string less than 50 characters with spaces: \n");
```

```
gets(string1);
```

```
printf("you entered:");
```

```
puts(string1);
```

```
printf("Enter the same string\n");
```

```
scanf("%s",string2);
```

```
printf("you entered:");
```

```
puts(string2);
```

```
}
```

## Example (2/2)

Sample output:

Enter a string less than 50 characters with spaces:

hello class

You entered: hello class

Enter the same string:

hello class

You entered: hello

# Common Errors

## **Syntax errors:**

Means you have typed something wrong

## **Run-time errors:**

Happens when the program tries to perform an illegal operation e.g. divide by 0, or input the wrong data type from the keyboard

## **Logic errors**

Due to a faulty algorithm e.g. an incorrect calculation or out of sequence statements.

# Next time

---

In lecture 3 next week we will be looking at:

- mathematical operations
- flow control

**Thank you for your attention 😊**

**See you in the laboratory...**
